1.0 SCOPE AND INTRODUCTION

1.1 Scope

1.2 Introduction

1.3 A Brief Description of the 717-200
1.0 SCOPE AND INTRODUCTION

1.1 Scope

This document provides, in a standardized format, airplane characteristics data for general airport planning. Since operational practices vary among airlines, specific data should be coordinated with the using airlines prior to facility design. Boeing Commercial Airplanes should be contacted for any additional information required.

Content of the document reflects the results of a coordinated effort by representatives from the following organizations:

1. Aerospace Industries Association
2. Airports Council International - North America
3. Air Transport Association of America
4. International Air Transport Association

The airport planner may also want to consider the information presented in the "CTOL Transport Aircraft, Characteristics, Trends, and Growth Projections," available from the US AIA, 1250 Eye St., Washington DC 20005, for long-range planning needs. This document is updated periodically and represents the coordinated efforts of the following organizations regarding future aircraft growth trends:

1. International Coordinating Council of Aerospace Industries Associations
2. Airports Council International - North America
3. Air Transport Association of America
4. International Air Transport Association
1.2 Introduction

This document conforms to NAS 3601. It provides characteristics of the Boeing Model 717-200 airplane for airport planners and operators, airlines, architectural and engineering consultant organizations, and other interested industry agencies. Airplane changes and available options may alter model characteristics; the data presented herein reflect typical airplanes in each model category.

For additional technical data or to contact the Boeing Airport Compatibility organization, please see the following webpage:

www.boeing.com/airports
1.3 A Brief Description of the 717-200 Airplane

The 717-200 is a twin-engine aircraft designed for short-haul short-field operations. It can carry 106 passengers in a mixed class configuration up to a range of approximately 2000 miles. It is designed to sustain daily 8 to 12 one-hour flights for fast turnaround at airport gates.

The 717-200 is powered by two advanced BMW/Rolls-Royce BR715 high-bypass-ratio engines. The BR715 engine is rated at 18,500 pounds of takeoff thrust, with lower fuel consumption, reduced exhaust emissions and significantly lower noise levels than the power plants on comparable airplanes. The thrust is uprated to 21,000 pounds for the high-gross-weight option airplanes.

An optional airstair under the main entry door number 1 allows operation at airports where there are no loading bridges or portable stairs.

2.0 AIRPLANE DESCRIPTION

2.1 General Characteristics

**Maximum Design Taxi Weight (MTW).** Maximum weight for ground maneuver as limited by aircraft strength and airworthiness requirements. (It includes weight of taxi and run-up fuel.)

**Maximum Design Landing Weight (MLW).** Maximum weight for landing as limited by aircraft strength and airworthiness requirements.

**Maximum Design Takeoff Weight (MTOW).** Maximum weight for takeoff as limited by aircraft strength and airworthiness requirements. (This is the maximum weight at start of the takeoff run.)

**Operating Empty Weight (OEW).** Weight of structure, powerplant, furnishing systems, unusable fuel and other unusable propulsion agents, and other items of equipment that are considered an integral part of a particular airplane configuration. Also included are certain standard items, personnel, equipment, and supplies necessary for full operations, excluding usable fuel and payload.

**Maximum Design Zero Fuel Weight (MZFW).** Maximum weight allowed before usable fuel and other specified usable agents must be loaded in defined sections of the aircraft as limited by strength and airworthiness requirements.

**Maximum Payload.** Maximum design zero fuel weight minus operational empty weight.

**Maximum Seating Capacity.** The maximum number of passengers specifically certificated or anticipated for certification.

**Maximum Cargo Volume.** The maximum space available for cargo.

**Usable Fuel.** Fuel available for aircraft propulsion.

NOTES: VERTICAL CLEARANCES SHOWN OCCUR DURING MAXIMUM VARIATIONS OF AIRPLANE ATTITUDE. COMBINATIONS OF AIRPLANE LOADING AND UNLOADING ACTIVITIES THAT PRODUCE THE GREATEST POSSIBLE VARIATIONS IN ATTITUDE WERE USED TO ESTABLISH THE VARIATIONS SHOWN. DURING ROUTINE SERVICING, THE AIRPLANE REMAINS RELATIVELY STABLE, PITCH AND ELEVATION CHANGES OCCURRING SLOWLY.

3.2 Payload/Range

3.3 F.A.R. Takeoff Runway Length Requirements

3.4 F.A.R. Landing Runway Length Requirements
3.0 AIRPLANE PERFORMANCE

3.1 General Information

The graph in Section 3.2 provides information on operating empty weight (OEW), payload, trip range, brake release gross weight, and fuel limits for a typical 717-200 airplane. To use this graph, if the trip range and zero fuel weight (OEW + payload) are known, the approximate brake release weight can be found, limited by fuel quantity.

The graphs in Section 3.3 provide information on F.A.R. takeoff runway length requirements with typical engines at different pressure altitudes. Maximum takeoff weights shown on the graphs are the heaviest for the particular airplane models with the corresponding engines. Standard day temperatures for pressure altitudes shown on the F.A.R. takeoff graphs are given below:

<table>

</tr>
</tbody>
</table>

Wet runway performance is shown in accordance with JAR-OPS 1 Subpart F, with wet runways defined in Paragraph 1.480(a)(10). Skid-resistant runways (grooved or PFC treated) per FAA or ICAO specifications exhibit runway length requirements that remove some or all of the length penalties associated with smooth (non-grooved) runways. Under predominantly wet conditions, the wet runway performance characteristics may be used to determine runway length requirements, if it is longer than the dry runway performance requirements.

The graph in Section 3.4 provides information on landing runway length requirements for different airplane weights and airport altitudes.

4.3 Clearance Radii
4.4 Visibility From Cockpit in Static Position
4.5 Runway and Taxiway Turn Paths
4.6 Runway Holding Bay
4.0 GROUND MANEUVERING

4.1 General Information

This section provides airplane turning capability and maneuvering characteristics. For ease of presentation, these data have been determined from the theoretical limits imposed by the geometry of the aircraft, and where noted, provide for a normal allowance for tire slippage. As such, they reflect the turning capability of the aircraft in favorable operating circumstances. These data should be used only as guidelines for the method of determination of such parameters and for the maneuvering characteristics of this aircraft.

In the ground operating mode, varying airline practices may demand that more conservative turning procedures be adopted to avoid excessive tire wear and reduce possible maintenance problems. Airline operating procedures will vary in the level of performance over a wide range of operating circumstances throughout the world. Variations from standard aircraft operating patterns may be necessary to satisfy physical constraints within the maneuvering area, such as adverse grades, limited area, or high risk of jet blast damage. For these reasons, ground maneuvering requirements should be coordinated with the using airlines prior to layout planning.

Section 4.2 shows turning radii for various nose gear steering angles. Radii for the main and nose gears are measured from the turn center to the outside of the tire.

Section 4.3 provides data on minimum width of pavement required for 180° turn.

Section 4.4 shows the pilot’s visibility from the cockpit and the limits of ambinocular vision through the windows. Ambinocular vision is defined as the total field of vision seen simultaneously by both eyes.

Section 4.5 shows wheel paths of a 717-200 on runway to taxiway, and taxiway to taxiway turns.

Section 4.6 illustrates a typical runway holding bay configuration.
NOTES:
* ACTUAL OPERATING TURNING RADII MAY BE GREATER THAN SHOWN.
* CONSULT WITH AIRLINE FOR SPECIFIC OPERATING PROCEDURE.
* R - 3 IS MEASURED TO OUTSIDE TIRE FACE.

5.0 TERMINAL SERVICING

5.1 Airplane Servicing Arrangement (Typical)
5.2 Terminal Operations, Turnaround Station
5.3 Terminal Operations, Enroute Station
5.4 Ground Servicing Connections
5.5 Engine Starting Pneumatic Requirements
5.6 Ground Pneumatic Power Requirements
5.7 Preconditioned Airflow Requirements
5.8 Ground Towing Requirements
5.0 TERMINAL SERVICING

During turnaround at the terminal, certain services must be performed on the aircraft, usually within a given time, to meet flight schedules. This section shows service vehicle arrangements, schedules, locations of service points, and typical service requirements. The data presented in this section reflect ideal conditions for a single airplane. Service requirements may vary according to airplane condition and airline procedure.

Section 5.1 shows typical arrangements of ground support equipment during turnaround. As noted, if the auxiliary power unit (APU) is used, the electrical, air start, and air-conditioning service vehicles would not be required. Passenger loading bridges or portable passenger stairs could be used to load or unload passengers.

Sections 5.2 and 5.3 show typical service times at the terminal. These charts give typical schedules for performing service on the airplane within a given time. Service times could be rearranged to suit availability of personnel, airplane configuration, and degree of service required.

Section 5.4 shows the locations of ground service connections in graphic and in tabular forms. Typical capacities and service requirements are shown in the tables. Services with requirements that vary with conditions are described in subsequent sections.

Section 5.5 shows typical sea level air pressure and flow requirements for engine start.

Section 5.6 shows air conditioning requirements for heating and cooling (pull-down and pull-up) using ground conditioned air. The curves show airflow requirements to heat or cool the airplane within a given time at ambient conditions.

Section 5.7 shows air conditioning requirements for heating and cooling to maintain a constant cabin air temperature using low pressure conditioned air. This conditioned air is supplied through an 8-in ground air connection (GAC) directly to the passenger cabin, bypassing the air cycle machines.

Section 5.8 shows ground towing requirements for various ground surface conditions.
5.1 AIRPLANE SERVICING ARRANGEMENT (TYPICAL)

MODEL 717-200

NOTE: * AUXILIARY POWER UNIT OR FIXED FACILITIES CAN ALSO PROVIDE
1. ELECTRICAL POWER
2. ENGINE START
3. AIR CONDITIONING
THIS DATA IS PROVIDED TO ILLUSTRATE THE GENERAL SCOPE AND TYPES OF TASKS INVOLVED IN TERMINAL OPERATIONS. VARYING AIRLINE PRACTICES AND OPERATING CIRCUMSTANCES THROUGHOUT THE WORLD WILL RESULT IN DIFFERENT SEQUENCES AND TIME INTERVALS TO ACCOMPLISH THE TASKS SHOWN.

**MAIN DECK SERVICE**
- Position Loading Bridge: 1.0
- Deplane Passengers: 4.8
- Service Galley: 11.3
- Service Cabin: 7.0
- Board Passengers: 8.8
- Remove Loading Bridge: 0.5

**LOWER DECK SERVICE**
- Unload Aft Compartment: 7.5
- Load Aft Compartment: 9.2
- Unload Fwd Compartment: 7.4
- Load Fwd Compartment: 9.1

**AIRCRAFT SERVICE**

5.5 ENGINE STARTING PNEUMATIC REQUIREMENTS

MODEL 717-200
5.6.1 GROUND PNEUMATIC POWER REQUIREMENTS – CABIN HEATING

Model 717-200

NOTES:

- Initial cabin temperature at 0°F (-17.8°C)
- Outside air temperature at 0°F (-17.8°C)
- No galley load, cloudy day, no lights
- Pressure = 12 to 70 psig at the ground connection
- Temperature at ground connection is 300°F (148.9°C).

Operational Notes:

1) Pack flow switch in "High" flow position
2) Temp selectors in "Auto" mode position

Diagram showing ground connect airflow in kg per minute versus time to heat cabin to 70°F (21.0°C) in minutes.
5.6.2 GROUND PNEUMATIC POWER REQUIREMENTS – CABIN COOLING

MODEL 717-200

NOTES:

INITIAL CABIN TEMPERATURE AT 108° F (42.2° C)
OUTSIDE AIR TEMPERATURE AT 103° F (39.4° C)
SOLAR LOAD 1775 BTU/HR, BRIGHT DAY, SOLAR IRRADIATION
NO GALLEY LOAD, DAY LIGHTING ON, NO PASSENGERS
PRESSURE = 12 TO 70 PSIG AT THE GROUND CONNECTION
TEMPERATURE AT GROUND CONNECTION IS 410° F (210° C).

OPERATIONAL NOTES:
1) PUMP FLOW SWITCH IN “HIGH” FLOW POSITION
2) TEMP SELECTORS IN “AUTO” MODE POSITION

MODEL 717-200
6.0 JET ENGINE WAKE AND NOISE DATA

6.1 Jet Engine Exhaust Velocities and Temperatures

6.2 Airport and Community Noise
6.0 JET ENGINE WAKE AND NOISE DATA

6.1 Jet Engine Exhaust Velocities and Temperature

This section shows exhaust velocity and temperature contours aft of the 717-200. The contours were calculated from a standard computer analysis using three-dimensional viscous flow equations with mixing of primary, fan, and free-stream flow. The presence of the ground plane is included in the calculations as well as engine tilt and toe-in. Mixing of flows from the engines is also calculated. The analysis does not include thermal buoyancy effects, which tend to elevate the jet wake above the ground plane. The buoyancy effects are considered to be small relative to the lateral velocity and therefore are not included.

The graphs show jet wake velocity and temperature contours for a representative engine. The results are valid for sea level, static, standard day conditions. The effect of wind on jet wakes was not included. There is evidence to show that a downwind or an upwind component does not simply add or subtract from the jet wake velocity, but rather carries the whole envelope in the direction of the wind. Crosswinds may carry the jet wake contour far to the side at large distances behind the airplane.

It should be understood, these exhaust velocity contours reflect steady-state, at maximum taxi weight, and not transient-state exhaust velocities. A steady-state is achieved with the aircraft in a fixed location, engine running at a given thrust level and measured when the contours stop expanding and stabilize in size, which could take several seconds. The steady-state condition, therefore, is conservative. Contours shown also do not account for performance variables such as ambient temperature or field elevation. For the terminal area environment, the transient-state is a more accurate representation of the actual exhaust contours when the aircraft is in motion and encountering static air with forward or turning movement, but it is very difficult to model on a consistent basis due to aircraft weight, weather conditions, the high degree of variability in terminal and apron configurations, and intensive numerical calculations. If the contours presented here are overly restrictive for terminal operations, The Boeing Company recommends conducting an analysis of the actual exhaust contours experienced by the using aircraft at the airport.

6.2 Airport and Community Noise

Airport noise is of major concern to the airport and community planner. The airport is a major element in the community's transportation system and, as such, is vital to its growth. However, the airport must also be a good neighbor, and this can be accomplished only with proper planning. Since aircraft noise extends beyond the boundaries of the airport, it is vital to consider the impact on surrounding communities. Many means have been devised to provide the planner with a tool to estimate the impact of airport operations. Too often they oversimplify noise to the point where the results become erroneous. Noise is not a simple subject; therefore, there are no simple answers.

The cumulative noise contour is an effective tool. However, care must be exercised to ensure that the contours, used correctly, estimate the noise resulting from aircraft operations conducted at an airport.

The size and shape of the single-event contours, which are inputs into the cumulative noise contours, are dependent upon numerous factors. They include the following:

1. Operational Factors
   (a) **Aircraft Weight**-Aircraft weight is dependent on distance to be traveled, en route winds, payload, and anticipated aircraft delay upon reaching the destination.
   (b) **Engine Power Settings**-The rates of ascent and descent and the noise levels emitted at the source are influenced by the power setting used.
   (c) **Airport Altitude**-Higher airport altitude will affect engine performance and thus can influence noise.

2. Atmospheric Conditions-Sound Propagation
   (a) **Wind**-With stronger headwinds, the aircraft can take off and climb more rapidly relative to the ground. Also, winds can influence the distribution of noise in surrounding communities.
   (b) **Temperature and Relative Humidity**-The absorption of noise in the atmosphere along the transmission path between the aircraft and the ground observer varies with both temperature and relative humidity.

3. Surface Condition-Shielding, Extra Ground Attenuation (EGA)
   (a) **Terrain**-If the ground slopes down after takeoff or up before landing, noise will be reduced since the aircraft will be at a higher altitude above ground. Additionally, hills, shrubs, trees, and large buildings can act as sound buffers.
All these factors can alter the shape and size of the contours appreciably. To demonstrate the effect of some of these factors, estimated noise level contours for two different operating conditions are shown below. These contours reflect a given noise level upon a ground level plane at runway elevation.

**Condition 1**

<tr>
<td>Humidity 70%</td>
<td></td>
</tr>
</tbody>
</table>
As indicated from these data, the contour size varies substantially with operating and atmospheric conditions. Most aircraft operations are, of course, conducted at less than maximum gross weights because average flight distances are much shorter than maximum aircraft range capability and average load factors are less than 100%. Therefore, in developing cumulative contours for planning purposes, it is recommended that the airlines serving a particular city be contacted to provide operational information.

In addition, there are no universally accepted methods for developing aircraft noise contours or for relating the acceptability of specific zones to specific land uses. It is therefore expected that noise contour data for particular aircraft and the impact assessment methodology will be changing. To ensure that the best currently available information of this type is used in any planning study, it is recommended that it be obtained directly from the Office of Environmental Quality in the Federal Aviation Administration in Washington, D.C.

It should be noted that the contours shown herein are only for illustrating the impact of operating and atmospheric conditions and do not represent the single-event contour of the family of aircraft described in this document. It is expected that the cumulative contours will be developed as required by planners using the data and methodology applicable to their specific study.
7.0 PAVEMENT DATA

7.1 General Information

7.8 Rigid Pavement Requirements - LCN Conversion

7.9 Rigid Pavement Requirements - FAA Method

7.10 ACN/PCN Reporting System - Flexible and Rigid Pavements

7.11 Tire Inflation Chart
7.0  PAVEMENT DATA

7.1  General Information

A brief description of the pavement charts that follow will help in their use for airport planning. Each airplane configuration is depicted with a minimum range of five loads imposed on the main landing gear to aid in interpolation between the discrete values shown. All curves for any single chart represent data based on rated loads and tire pressures considered normal and acceptable by current aircraft tire manufacturer's standards. Tire pressures, where specifically designated on tables and charts, are at values obtained under loaded conditions as certificated for commercial use.

Section 7.2 presents basic data on the landing gear footprint configuration, maximum design taxi loads, and tire sizes and pressures.

Maximum pavement loads for certain critical conditions at the tire-to-ground interface are shown in Section 7.3, with the tires having equal loads on the struts.

Pavement requirements for commercial airplanes are customarily derived from the static analysis of loads imposed on the main landing gear struts. The charts in Section 7.4 are provided in order to determine these loads throughout the stability limits of the airplane at rest on the pavement. These main landing gear loads are used as the point of entry to the pavement design charts, interpolating load values where necessary.

The flexible pavement design curves (Section 7.5) are based on procedures set forth in Instruction Report No. S-77-1, "Procedures for Development of CBR Design Curves," dated June 1977, and as modified according to the methods described in FAA Advisory Circular 150/5320-6D, “Airport Pavement Design and Evaluation”, dated July 7, 1995. Instruction Report No. S-77-1 was prepared by the U.S. Army Corps of Engineers Waterways Experiment Station, Soils and Pavements Laboratory, Vicksburg, Mississippi. The line showing 10,000 coverages is used to calculate Aircraft Classification Number (ACN).
The following procedure is used to develop the curves, such as shown in Section 7.5:

1. Having established the scale for pavement depth at the bottom and the scale for CBR at the top, an arbitrary line is drawn representing 10,000 coverages.

2. Values of the aircraft weights on the main landing gear are then plotted.

3. Additional annual departure lines are drawn based on the load lines of the aircraft gross weights already established.

All Load Classification Number (LCN) curves (Sections 7.6 and 7.8) have been developed from a computer program based on data provided in International Civil Aviation Organization (ICAO) document 9157-AN/901, *Aerodrome Design Manual*, Part 3, “Pavements”, Second Edition, 1983. LCN values are shown directly for parameters of weight on main landing gear, tire pressure, and radius of relative stiffness (l) for rigid pavement or pavement thickness or depth factor (h) for flexible pavement.

Rigid pavement design curves (Section 7.7) have been prepared with the Westergaard equation in general accordance with the procedures outlined in the *Design of Concrete Airport Pavement* (1955 edition) by Robert G. Packard, published by the American Concrete Pavement Association, 3800 North Wilke Road, Arlington Heights, Illinois 60004-1268. These curves are modified to the format described in the Portland Cement Association publication XP6705-2, *Computer Program for Airport Pavement Design (Program PDILB)*, 1968, by Robert G. Packard.

The following procedure is used to develop the rigid pavement design curves shown in Section 7.7:

1. Having established the scale for pavement thickness to the left and the scale for allowable working stress to the right, an arbitrary load line is drawn representing the main landing gear maximum weight to be shown.

2. Values of the subgrade modulus (k) are then plotted.

3. Additional load lines for the incremental values of weight on the main landing gear are drawn on the basis of the curve for k = 300, already established.
The ACN/PCN system (Section 7.10) as referenced in ICAO Annex 14, "Aerodromes," First Edition, July 1990, provides a standardized international airplane/pavement rating system replacing the various S, T, TT, LCN, AUW, ISWL, etc., rating systems used throughout the world. ACN is the Aircraft Classification Number and PCN is the Pavement Classification Number. An aircraft having an ACN equal to or less than the PCN can operate on the pavement subject to any limitation on the tire pressure. Numerically, the ACN is two times the derived single-wheel load expressed in thousands of kilograms, where the derived single wheel load is defined as the load on a single tire inflated to 181 psi (1.25 MPa) that would have the same pavement requirements as the aircraft. Computationally, the ACN/PCN system uses the PCA program PDILB for rigid pavements and S-77-1 for flexible pavements to calculate ACN values. The method of pavement evaluation is left up to the airport with the results of their evaluation presented as follows:

<table>
<thead>
<tr>
<th>PCN</th>
<th>PAVEMENT TYPE</th>
<th>SUBGRADE CATEGORY</th>
<th>TIRE PRESSURE CATEGORY</th>
<th>EVALUATION METHOD</th>

<td>Z = To 73 psi (0.5 MPa)</td>
<td></td>
</tr>
</tbody>
</table>

Section 7.10.1 shows the aircraft ACN values for flexible pavements. The four subgrade categories are:

- Code A - High Strength - CBR 15
- Code B - Medium Strength - CBR 10
- Code C - Low Strength - CBR 6
- Code D - Ultra Low Strength - CBR 3

Section 7.10.2 shows the aircraft ACN values for rigid pavements. The four subgrade categories are:

- Code A - High Strength, \( k = 550 \text{ pci} (150 \text{ MN/m}^3) \)
- Code B - Medium Strength, \( k = 300 \text{ pci} (80 \text{ MN/m}^3) \)
- Code C - Low Strength, \( k = 150 \text{ pci} (40 \text{ MN/m}^3) \)
- Code D - Ultra Low Strength, \( k = 75 \text{ pci} (20 \text{ MN/m}^3) \)

7.3 MAXIMUM PAVEMENT LOADS
MODEL 717-200
7.4.1 LANDING GEAR LOADING ON PAVEMENT
MODEL 717-200
7.4.2 LANDING GEAR LOADING ON PAVEMENT

MODEL 717-200
7.4.3 LANDING GEAR LOADING ON PAVEMENT
MODEL 717-200
7.5 Flexible Pavement Requirements - U.S. Army Corps of Engineers Method
(S-77-1)

The following flexible-pavement design chart presents the data of five incremental main-gear loads at the minimum tire pressure required at the maximum design taxi weight.

In the example shown on the next page, for a CBR of 12 and an annual departure level of 6,000, the required flexible pavement thickness for an airplane with a main gear loading of 100,000 pounds is 17.2 inches.

The line showing 10,000 coverages is used for ACN calculations (see Section 7.10).

The FAA design method uses a similar procedure using total airplane weight instead of weight on the main landing gears. The equivalent main gear loads for a given airplane weight could be calculated from Section 7.4.
7.5 FLEXIBLE PAVEMENT REQUIREMENTS - U.S. ARMY CORPS OF ENGINEERS
DESIGN METHOD (S-77-1)
MODEL 717-200
7.6 Flexible Pavement Requirements - LCN Method

To determine the airplane weight that can be accommodated on a particular flexible pavement, both the Load Classification Number (LCN) of the pavement and the thickness must be known.

In the example shown on the next page, flexible pavement thickness is shown at 9.8 in. with an LCN of 50. For these conditions, the maximum allowable weight permissible on the main landing gear is 115,200 lb for an airplane with 164-psi main gear tires.

Note: If the resultant aircraft LCN is not more that 10% above the published pavement LCN, the bearing strength of the pavement can be considered sufficient for unlimited use by the airplane. The figure 10% has been chosen as representing the lowest degree of variation in LCN that is significant (reference: ICAO Aerodrome Manual, Part 2, "Aerodrome Physical Characteristics," Chapter 4, Paragraph 4.1.5.7v, 2nd Edition dated 1965).
7.6 FLEXIBLE PAVEMENT REQUIREMENTS - LCN METHOD

MODEL 717-200
7.7 Rigid Pavement Requirements - Portland Cement Association Design Method

The following rigid pavement design chart presents the data for five incremental main gear loads at the minimum tire pressure required at the maximum design taxi weight.

In the example shown in the next page, for an allowable working stress of 550 psi, a main gear load of 115,200 lb, and a subgrade strength (k) of 150, the required rigid pavement thickness is 9.4 in.
7.7 RIGID PAVEMENT REQUIREMENTS – PORTLAND CEMENT ASSOCIATION METHOD

FOR LOADS LESS THAN MAXIMUM, THE CURVES ARE EXACT FOR K = 300 BUT DEVIATE SLIGHTLY FOR OTHER VALUES OF K.

REFERENCES:
"DESIGN OF CONCRETE AIRPORT PAVEMENT" AND "COMPUTER PROGRAM FOR AIRPORT PAVEMENT DESIGN - PROGRAM FDILB" PORTLAND CEMENT ASSOCIATION.
7.8 Rigid Pavement Requirements - LCN Conversion

To determine the airplane weight that can be accommodated on a particular rigid pavement, both the LCN of the pavement and the radius of relative stiffness (l) of the pavement must be known.

In the example shown in Section 7.8.2, for a rigid pavement with a radius of relative stiffness of 54 and an LCN of 60, the maximum allowable weight permissible on the main landing gear is 100,000 lb for an airplane with 164-psi main tires.

Note: If the resultant aircraft LCN is not more that 10% above the published pavement LCN, the bearing strength of the pavement can be considered sufficient for unlimited use by the airplane. The figure 10% has been chosen as representing the lowest degree of variation in LCN that is significant (reference: ICAO Aerodrome Manual, Part 2, "Aerodrome Physical Characteristics," Chapter 4, Paragraph 4.1.5.7v, 2nd Edition dated 1965).

MAXIMUM POSSIBLE MAIN GEAR LOAD AT MAXIMUM DESIGN TAXI WEIGHT AND AFT CG (122,000 LB MTW)

RADIUS OF RELATIVE STIFFNESS, \( \delta \)
7.9 Rigid Pavement Requirements - FAA Design Method

The following rigid pavement design chart presents data on five incremental main gear weights at
the minimum tire pressure required at the maximum design taxi weight.

In the example shown, the pavement flexural strength is shown at 650 psi, the subgrade strength is
shown at k = 150, and the annual departure level is 6,000. For these conditions, the required rigid
pavement thickness for an airplane with a main gear loading of 100,000 pounds is 11.0 inches.
7.10 ACN/PCN Reporting System - Flexible and Rigid Pavements

To determine the ACN of an aircraft on flexible or rigid pavement, both the aircraft gross weight and the subgrade strength category must be known. In the chart in Section 7.10.1, for an aircraft with gross weight of 106,000 lb and medium subgrade strength (Code A), the flexible pavement ACN is 26.5. In Section 7.10.4, for the same gross weight and medium subgrade strength (Code A), the rigid pavement ACN is 29.5.

Note: An aircraft with an ACN equal to or less that the reported PCN can operate on that pavement subject to any limitations on the tire pressure. (Ref.: ICAO Annex 14 Aerodromes, First Edition, July 1990.)

The following table provides ACN data in tabular format similar to the one used by ICAO in the “Aerodrome Design Manual Part 3, Pavements”. If the ACN for an intermediate weight between maximum taxi weight and the empty weight of the aircraft is required, Figures 7.10.1 through 7.10.6 should be consulted.

7.10.1 AIRCRAFT CLASSIFICATION NUMBER - FLEXIBLE PAVEMENT - 115,000 LB MTW

MODEL 717-200

NOTES:

* TIRES - H41 x 15.0 - 19, 24PR
* PRESSURE - 158 PSI (11.11 KG/SQ CM)

CODE A - CBR 15 (HIGH)
CODE B - CBR 10 (MEDIUM)
CODE C - CBR 8 (LOW)
CODE D - CBR 3 (ULTRA LOW)

NOTES:
1. ACN WAS DETERMINED AS REFERENCED IN AMMENDMENT 3B TO ICAO ANNEX 14 "AERODROMES", 8TH EDITION, MARCH 1983
2. TO DETERMINE MAIN LANDING GEAR LOADING, SEE SECTION 7.4.
3. PERCENT WEIGHT ON MAIN LANDING GEAR: 98.2
7.10.2 AIRCRAFT CLASSIFICATION NUMBER - FLEXIBLE PAVEMENT – 119,000 LB MTW
MODEL 717-200

NOTES:
1. ACN was determined as referenced in AMENDMENT 38 to ICAO ANNEX 14.
2. To determine main landing gear loading.
3. Percent weight on main landing gear: 95.9.
7.10.3 AIRCRAFT CLASSIFICATION NUMBER - FLEXIBLE PAVEMENT – 122,000 LB MTW

MODEL 717-200

NOTES:
* TIRES - H41 x 15.0 - 19, 24PR
* PRESSURE - 164 PSI (11.55 KG/SQ CM)

CODE D = CBR 3 (ULTRA LOW)
CODE C = CBR 8 (LOW)
CODE B = CBR 10 (MEDIUM)
CODE A = CBR 15 (HIGH)

NOTES:
1. ACN WAS DETERMINED AS REFERENCED IN AMENDMENT 3B TO ICAO ANNEX 14 "AERODROMES", 8TH EDITION, MARCH 1983
2. TO DETERMINE MAIN LANDING GEAR LOADING, SEE SECTION 7.4.
3. PERCENT WEIGHT ON MAIN LANDING GEAR: 94.4
7.10.4 AIRCRAFT CLASSIFICATION NUMBER - RIGID PAVEMENT – 115,000 LB MTW

MODE 777-200

NOTES:
- TIRES - H41 x 15.0 - 19, 24PR
- PRESSURE - 158 PSI (11.11 KG/SQ CM)

CODE D - k = 75 (ULTRA LOW)
CODE C - k = 150 (LOW)
CODE B - k = 300 (MEDIUM)
CODE A - k = 550 (HIGH)

1. ACN WAS DETERMINED AS REFERENCED IN AMENDMENT 5B TO ICAO ANNEX 14 “AERODROMES”, 5TH EDITION, MARCH 1983
2. TO DETERMINE MAIN LANDING GEAR loadsING, SEE SECTION 7.4.
3. PERCENT WEIGHT ON MAIN LANDING GEAR: 96.1

AIRCRAFT GROSS WEIGHT

(1,000 LB)

(1,000 KG)
7.10.5 AIRCRAFT CLASSIFICATION NUMBER - RIGID PAVEMENT – 119,000 LB MTW

NOTES:
* TIRES - H41 x 15.0 - 19, 24PR
* PRESSURE = 164 PSI (11.55 KG/SQ CM)

CODE D - k = 75 (ULTRA LOW)
CODE C - k = 150 (LOW)
CODE B - k = 300 (MEDIUM)
CODE A - k = 650 (HIGH)

NOTES:
1. ACN WAS DETERMINED AS REFERENCED IN AMENDMENT 35 TO ICAO ANNEX 14 "AERODROMES", 8TH EDITION, MARCH 1983
2. TO DETERMINE MAIN LANDING GEAR LOADING, SEE SECTION 7.4.
3. PERCENT WEIGHT ON MAIN LANDING GEAR: 95.9
7.10.6 AIRCRAFT CLASSIFICATION NUMBER - RIGID PAVEMENT - 122,000 LB MTW

NOTES:
* TIRES - H41 x 15.0 - 19, 24PR
* PRESSURE - 164 PSI (11.53 KG/SQ CM)

CODE D - k = 75 (ULTRA LOW)
CODE C - k = 150 (LOW)
CODE B - k = 300 (MEDIUM)
CODE A - k = 550 (HIGH)

NOTES:
1. ACN WAS DETERMINED AS REFERENCED IN AMENDMENT 38 TO ICAO ANNEX 14 "AERODROMES", 8TH EDITION, MARCH 1983
2. TO DETERMINE MAIN LANDING GEAR LOADING, SEE SECTION 7.4.
3. PERCENT WEIGHT ON MAIN LANDING GEAR: 94.4
7.11 TIRE INFLATION CHART
MODEL 717-200
8.0 FUTURE 717 DERIVATIVE AIRPLANES
8.0 FUTURE 717 DERIVATIVE AIRPLANES

Development of these derivatives will depend on airline requirements. The impact of airline requirements on airport facilities will be a consideration in the configuration and design of these derivatives.
